Strict Lyapunov Function Constructions Under LaSalle Conditions with an Application to Lotka-Volterra Systems

Frédéric Mazenc and Michael Malisoff

Abstract—We provide new techniques for building explicit global strict Lyapunov functions for broad classes of periodic time varying nonlinear systems satisfying LaSalle conditions. We illustrate our work using the Lotka-Volterra model, which plays a fundamental role in bioengineering. We use our strict Lyapunov constructions to prove robustness of the Lotka-Volterra tracking dynamics to uncertainty in the death rates.

Index Terms—Lyapunov function, LaSalle conditions, biological systems

I. INTRODUCTION

YAPUNOV functions provide vital tools for the analysis of, and controller design for, nonlinear systems [8], [9], [18]. The two main types of Lyapunov functions are strict Lyapunov functions (also called strong Lyapunov functions, having negative definite time derivatives along trajectories) and nonstrict Lyapunov functions (also called weak Lyapunov functions, whose time derivatives along the trajectories are negative semidefinite); see Section II for precise definitions.

Strict Lyapunov functions are typically far more useful than nonstrict ones. In general, nonstrict Lyapunov functions can only be used to prove asymptotic stability, using, e.g., the LaSalle invariance principle. On the other hand, strict Lyapunov functions can often be used to show robustness properties, such as input-to-state stability (ISS) (but see [10] for an alternative stability proof based on weak Lyapunov functions for time-varying systems). Robustness is essential in engineering, due to uncertainty and controller noise. For this reason, it is important to construct strict Lyapunov functions, even for systems that are already known to be UGAS.

Moreover, many controller methods (e.g., forwarding [16], [18] and universal stabilizing controllers [19]) use strict Lyapunov functions. For example, if \( V \) is a strict Lyapunov function for a system \( \dot{x} = f(t, x) \) for which \( \alpha(x) := \inf_{x_0} \{-[V_x(t, x) + V_z(t, x)f(t, x)]\} \) is radially unbounded, with \( f \) and \( g \) locally Lipschitz, and with \( V, f, \) and \( g \) all periodic in \( t \) with the same period \( T \), then \( \dot{x} = f(t, x) + g(t, x)[K(t, x) + d] \) is input-to-state stable if \( K(t, x) = -\frac{x}{|x|}g(t, x)\). In fact, along the trajectories of the closed loop system, the triangle inequality gives the ISS Lyapunov decay condition \( \dot{V} \leq -\alpha(x) - |V_x(t, x)g(t, x)|^2 + V_x(t, x)g(t, x) \leq -\alpha(x) - 0.5|V_x(t, x)g(t, x)|^2 + 0.5|d|^2 \leq -\alpha(x) + 0.5|x|^2 \). (The radial unboundedness of \( \alpha \) is needed for the ISS Lyapunov function decay condition, since if \( \alpha \) were only positive definite, then we could only guarantee integral ISS. On the other hand, one can first replace \( V \) with \( \kappa(V) \) for a suitable function \( \kappa \) to guarantee that \( \alpha \) is proper [20].) Consequently, when a global strict Lyapunov function is known, many important stabilization problems can be solved almost immediately.

In general, it is much easier to construct nonstrict Lyapunov functions, owing to the more restrictive decay condition for strict Lyapunov functions. For instance, when a passive nonlinear system is stabilized by linear output feedback, the energy (i.e., storage) function can typically be used as the weak Lyapunov function. This is useful for electro-mechanical systems. When a system is stabilized via the Jurdjevic-Quinn theorem, nonstrict Lyapunov functions are typically available, e.g., using the Hamiltonian for Euler Lagrange systems [5], [7],[13],[17]. If a system is known to be UGAS, then converse Lyapunov function theory typically guarantees the existence of a strict Lyapunov function. However, the Lyapunov functions provided by converse theory are often abstract and nonexplicit, and therefore may not always lend themselves to applications. This has also motivated a significant literature on constructing strict Lyapunov functions, e.g., [1], [5].

In this work, we present two new strict Lyapunov function constructions, based on transforming nonstrict Lyapunov functions into strict ones, under Lie derivative conditions. The assumptions for our first construction are more general than those of [15] and different from those of [12, Corollary 2]. This is because we allow periodic time varying systems, including cases where all of the higher order Lie derivatives are allowed to vanish at some points outside the equilibrium, on some time intervals. Our construction is simpler than the one in [15], even in the special case of time invariant systems.

Our second result uses the Matrosov approach. In general, Matrosov’s method can be difficult to apply, because one needs to find the necessary auxiliary functions. Here we give simple sufficient conditions leading to a systematic design of auxiliary functions. The auxiliary functions we construct differ from the ones that are implicitly given in [12], and they lead to strict Lyapunov functions using the Matrosov construction from [14]. In fact, our strict Lyapunov functions have the property that their Lie derivatives are frequently
bounded above by negative definite quadratic functions. Another important feature of our work is that it applies to cases where the state space of the system is a general subset of Euclidean space, instead of the whole Euclidean space. This is desirable for biological systems, whose state spaces are often restricted by the requirement that physical quantities need to be nonnegative. We illustrate our approach using an error dynamics associated with the Lotka-Volterra system, which plays a fundamental role in bioengineering.

II. Definitions and Assumptions

Throughout this work, $\mathcal{X}$ is any open subset of $\mathbb{R}^n$ containing the origin. Consider a nonlinear time varying dynamics

$$\dot{x} = f(t, x), \quad x \in \mathcal{X}$$

(1)

where $f : [0, \infty) \times \mathcal{X} \to \mathbb{R}^n$ is $C^\infty$. $\mathcal{X}$ is positively invariant for (1), and $f(t, 0) = 0$ for all $t \geq 0$. We always assume that (1) is periodic of period $T$ in $t$, meaning there is a constant $T > 0$ so that $f(t+T, x) = f(t, x)$ for all $(t, x) \in [0, \infty) \times \mathcal{X}$. We further assume that $f$ is Lipschitz complete, meaning for each initial condition $x(t_0) = x_0$ with $t_0 \geq 0$ and $x_0 \in \mathcal{X}$, the solution $x(t, t_0, x_0)$ for the corresponding initial value problem for (1) is uniquely defined on $[t_0, \infty)$. Set $\mathbb{N} = \{1, 2, 3, \ldots\}$. Given a $C^\infty$ function $V : [0, \infty) \times \mathcal{X} \to \mathbb{R}$, we set

$$a_0(t, x) = V(t, x), \quad \text{and} \quad a_r(t, x) = -\frac{\partial a_{r-1}}{\partial t}(t, x)f(x, t) - \frac{\partial^2 a_{r-1}}{\partial x^2}(t, x) \quad \forall r \in \mathbb{N}.$$ (2)

If $V$ and $f$ are time invariant, then $a_r = (-1)^r L_f^r V$ for all $r \geq 1$, where $L_f^r$ is the usual iterated Lie derivative defined by

$$L_f^0 V = V, \quad L_f^1 V(x) = L_f V(x) = \frac{\partial V}{\partial x}(x)f(x, x), \quad \text{and} \quad L_f^k V = L_f(L_f^{k-1} V) \quad \forall k \geq 2.$$ (3)

Also, if we use $\tilde{G} = (\partial G/\partial t)(t, x) + (\partial G/\partial x)(t, x)f(t, x)$ for any $C^1$ function $G$, then $\tilde{a}_r = -a_{r+1}$ for all $r \geq 1$. A continuous function $k : [0, \infty) \to [0, \infty)$ is of class $\mathcal{K}_\infty$ (written $k \in \mathcal{K}_\infty$) provided it is zero at zero, strictly increasing and unbounded. A function $G : [0, \infty) \times \mathcal{X} \to \mathbb{R}$ is positive definite (resp., positive semi-definite) on $\mathcal{X}$ provided $G(t, 0) = 0$ for all $t \geq 0$ and $\inf \{G(t, x) : t \geq 0\} > 0$ (resp., $\geq 0$) for all $x \in \mathcal{X} \setminus \{0\}$. A function $G$ is negative (semi-)definite provided $-G$ is positive (semi-)definite. We use $\cdot_{\mathcal{X}}$ to denote the usual Euclidean norm.

A function $V : [0, \infty) \times \mathcal{X} \to \mathbb{R}$ is called a storage function provided there are continuous positive definite functions $\alpha_1, \alpha_2 : \mathcal{X} \to [0, \infty)$ such that (I) for each $i, \alpha_i(q) \to +\infty$ whenever $|q| \to \infty$ with $q$ remaining in $\mathcal{X}$ (i.e., $\alpha_i(q_t) \to +\infty$ for each $i$ and each unbounded sequence $\{q_t\}$ that remains in $\mathcal{X}$, which is true vacuously if $\mathcal{X}$ is bounded) and (II) $\alpha_1(x) \leq V(t, x) \leq \alpha_2(x)$ for all $(t, x) \in [0, \infty) \times \mathcal{X}$. A $C^1$ storage function $V$ is called a nonstrict (resp., strict) Lyapunov-like function for (1) provided $-\alpha_1(t, x)$ is negative semi-definite (resp., negative definite). If, in addition, for each $i$ and each boundary point $q \in \partial \mathcal{X}$, $\alpha_i(q) \to +\infty$ when $q \to q$, then a nonstrict (resp., strict) Lyapunov-like function is called a nonstrict (resp., strict) Lyapunov function. The existence of strict Lyapunov functions is key to proving uniform global asymptotic stability (UGAS) [14].

III. First Construction: Iterated Lie Derivatives

To motivate our assumptions, suppose that a given $C^\infty$ time invariant system $\dot{x} = f(x)$, satisfying $f(0) = 0$ and evolving on $\mathbb{R}^n$, admits a time invariant $C^\infty$ nonstricter Lyapunov function $V$ such that for each $q \in \mathbb{R}^n \setminus \{0\}$, there is an $i \in \mathbb{N}$ such that $L_f^i V(q) \neq 0$, e.g., conditions (i)-(ii) in Theorem 1 below hold, and (3) holds independently of $t$. If $L_f^k V(x(t, x_0)) \equiv 0$ along some trajectory $t \mapsto x(t, x_0)$ of the system, then we can differentiate repeatedly in time to get $L_f^k V(x(t, x_0)) \equiv 0$ for all $t \geq 0$ and all $k \in \mathbb{N}$, so $L_f^k V(x_0) = 0$ for all $k \in \mathbb{N}$. By assumption, this implies that $x_0 = 0$. Hence, UGAS follows from LaSalle invariance. However, it is not clear how to construct a global strict Lyapunov function. This motivates our (more general) hypotheses in the following theorem:

Theorem 1: Consider the periodic time varying system (1) with state space $\mathcal{X} = \mathbb{R}^n$ and some period $T > 0$ in $t$, where $f \in C^\infty$. Assume that there exists a $C^\infty$ storage function $V : [0, \infty) \times \mathbb{R}^n \to [0, \infty)$ having period $T$ in $t$ such that the following hold: (i) $V$ is a nonstrict Lyapunov function for (1) and (ii) there exist a constant $\tau \in [0, T)$, a constant $\ell \in \mathbb{N}$, and a positive definite continuous function $\rho$ such that for all $x \in \mathbb{R}^n$ and all $t \in [0, \tau]$,

$$\alpha_1(t, x) + \sum_{m=2}^{\ell} a_m^2(t, x) \geq \rho(V(t, x)).$$ (4)

Then we can explicitly determine functions $F_j$ and $G$, with $G$ periodic of period $T$ in $t$, such that

$$V^2(t, x) = \sum_{j=1}^{T-1} F_j(V(t, x)) A_j(t, x) + G(t, V(t, x)),$$ (5)

where $A_j(t, x) = \sum_{m=1}^j a_{m+1}(t, x)a_m(t, x) \quad \forall j$

is a strict Lyapunov function for (1), giving UGAS of (1).

Remark 1: Theorem 1 remains true if $V$ is merely $C^{\ell+1}$ (instead of $C^\infty$). The assumptions of Theorem 1 are related to, but more general than, those of the strict Lyapunov function construction from [15] and different from those of [12, Corollary 2]. The assumptions of [15] are the special case of (i)-(ii) in which $f$ and $V$ are time invariant; in that case, (3) says there is a continuous positive definite function $\rho$ so that $-L_f^k V(x) + \sum_{m=2}^{\ell} (L_f^m V(x))^2 \geq \rho(V(x))$ for all $x \in \mathbb{R}^n$. Our result is new, even in this special case, because the strict Lyapunov function construction in our proof of Theorem 1 is simpler than the one in [15]; see Remark 2 at the end of Section V for details. It is important to have strict Lyapunov functions that are as simple as possible for feedback design and robustness analysis. We prove Theorem 1 in Section V.

IV. Second Construction: Matrosov Conditions

To simplify the notation in our next theorem, we only consider time invariant systems

$$\dot{x} = f(x), \quad x \in \mathcal{X}$$ (5)
for which \( X \subseteq \mathbb{R}^n \) is positively invariant, where \( f(0) = 0 \); see Remark 5 in Section VI for the generalization to \( (1) \). We use the Matrosov approach from [14] to construct global strict Lyapunov functions for \((5)\). In addition to a nonstrict Lyapunov function, the Matrosov results in [14] require appropriate auxiliary functions, which can be difficult to find in practice. The paper [14] does not provide any general methods for constructing auxiliary functions.

Our next theorem provides a new mechanism for choosing auxiliary functions. However, its most important features are that \((A)\) it applies to systems whose state space is only a subset of \( \mathbb{R}^n \) and \((B)\) it may yield Lyapunov functions that are simpler than other constructions, and that also have desirable local properties, such as local boundedness from below by positive definite quadratic functions; see Section VII-B. For the rest of this work, we assume that all of our functions are sufficiently smooth. Our Matrosov-type assumption is:

**Assumption 1:** There exist a storage function \( V_1 : X \to [0, \infty) \); functions \( h_1, \ldots, h_m \) such that \( h_j(0) = 0 \) for all \( j \); everywhere positive functions \( r_1, \ldots, r_m \) and \( \rho \); and an integer \( N > 0 \) for which

\[
\nabla V_1(x)f(x) \leq -r_1(x)h_1(x) - \ldots - r_m(x)h_m(x)
\]

and

\[
\sum_{i=0}^{N} \sum_{j=1}^{m} [L_i^j h_j(x)]^2 \geq \rho(V_1(x))V_1(x)
\]

hold for all \( x \in X \). Moreover, \( f \) is defined on \( \mathbb{R}^n \), and there is a function \( \bar{f} \in \mathcal{K}_{\infty} \) such that

\[
\|f(x)\| \leq \bar{f}(\|x\|) \quad \forall x \in \mathbb{R}^n.
\]

Also, \( V_1 \) has a positive definite quadratic lower bound in some neighborhood of the origin.

In Section VI, we prove:

**Theorem 2:** If \((5)\) satisfies Assumption 1, then one can determine explicit functions \( k_1, \ldots, k_{\ell-1} \in \mathcal{K}_{\infty} \cap C^1 \) and an everywhere positive function \( q \in C^1 \) such that

\[
S(x) = \sum_{i=1}^{N} \Omega_i \left( k_i(V_1(x)) + V_i(x) \right)
\]

with the choices

\[
V_i(x) = -\sum_{i=1}^{m} L_{i}^{j-1} h_l(x) L_{i}^{j-1} h_l(x), \quad i = 2, \ldots, N
\]

satisfies

\[
S(x) \geq V_1(x)
\]

and

\[
\nabla S(x)f(x) \leq -q(x)V_1(x)
\]

for all \( x \in X \). If, in addition, \( X = \mathbb{R}^n \), then the system \((5)\) is GAS.

Throughout what follows, all inequalities should be understood to hold globally unless otherwise indicated, and we leave out the arguments of our functions when they are clear.

**V. PROOF OF THEOREM 1**

1) **Formula for Strict Lyapunov Function:** We can assume that \( \ell \geq 3 \), by enlarging \( \ell \) as needed without relabeling. We show that \((1)\) admits the global strict Lyapunov function

\[
V^2(t,x) = V(t,x)S_2(t,x) + \kappa(V(t,x))V(t,x),
\]

where \( S_2(t,x) = S_1(t,x) + S_2(t,x) \),

\[
S_1(t,x) = \sum_{p=1}^{\ell-1} k_p(V(t,x)) M_p(t,x) + k_0(\mathcal{V}(x)) V(t,x),
\]

\[
S_2(t,x) = G(V(t,x)) + \frac{1}{T} \left( \int_{t-s}^{t} \int_{s}^{t} q(r) dr ds \right) + k_{l-1}(V(t,x)) \frac{\omega(V(t,x))}{K(V(t,x))},
\]

and

\[
M_p(t,x) = \sum_{m=1}^{p} a_{m+1}(t,x) a_m(t,x) + \int_{0}^{\tau} \Gamma(r) dr
\]

for \( p = 1, 2, \ldots, \ell - 1 \). Here \( \kappa \in C^1 \) is any strictly increasing function such that

\[
\kappa(V(t,x)) \geq |S_2(t,x)| + 1
\]

for all \( (t,x) \in [0, \infty) \times \mathbb{R}^n \), \( \Gamma \in C^1 \) is any everywhere positive increasing function such that

\[
\Gamma(V(t,x)) \geq (\ell + 2)|a_m(t,x)| + 1
\]

for all \( m \in \{1, \ldots, \ell + 1\} \) and all \( (t,x) \in [0, \infty) \times \mathbb{R}^n \), \( \omega \in \mathcal{K}_{\infty} \cap C^1 \) and the strictly increasing everywhere positive function \( K \in C^1 \) are such that

\[
\rho(r) \geq \frac{\omega(r)}{K(r)} \quad \forall r \geq 0,
\]

the \( C^1 \) positive definite functions \( k_1, k_2, \ldots, k_{\ell-1} \) are

\[
k_{\ell-1}(v) = \omega^{2-\ell-1}(v)
\]

and

\[
k_p(v) = k_{\ell-1}(v) \Omega^{2-\ell-n-1}(v)
\]

for \( p = 1, 2, \ldots, \ell - 2 \),

where

\[
\Omega(v) = \frac{2\tau \omega(v)}{3T(\ell - 2)K(v)K(v)},
\]

\( k_0 \) is any \( C^1 \) increasing function such that

\[
k_0(V(t,x)) + k_0'(V(t,x)) V(t,x) \geq \sum_{p=1}^{\ell-1} |k_p'(V(t,x))| |M_p(t,x)| + 1
\]

\[
q : \mathbb{R} \to [0, \infty] \text{ is any continuous function with period } T \text{ that satisfies } q(t) = 0 \text{ for all } t \in [\tau, T] \text{ and } q(t) = 1 \text{ for all } t \in [\tau, 2T] \text{, and } G \text{ is any } C^1 \text{ function such that}
\]

\[
G'(v) \geq
\]

\[
\frac{T}{k_{\ell-1}(v)} \frac{\omega(v) K(v) - \omega(v) K'(v)}{K(v)} + k_{\ell-1}(v) \frac{\omega(v)}{K(v)}
\]

for all \( v \geq 0 \). The functions \( \omega \) and \( K \) can be obtained using Lemma A.1 below, \( \Gamma \) can be obtained by majorizing \( s \mapsto 1 + \max\{1 + |(\ell + 2)|a_m(t,x)| : t \geq 0, x \in X, m \in \{1, 2, \ldots, \ell + 1\}, V(t,x) \leq s\} \) by a \( C^1 \) function, and \( k_0 \) can be obtained.
because each $M_p$ is periodic in $t$ and $V$ is a storage function that is also periodic in $t$. The theorem will then follow by collecting the functions involving $V$ to produce (4).

2) Stability Analysis: To show that (10) is a strict Lyapunov function for (1), we use the everywhere nonnegative functions

$$N_j(t, x) = \sum_{m=2}^{j+1} a_m^2(t, x) + a_1(t, x)$$

for $1 \leq j \leq \ell - 1$, which have period $T$ in $t$. By (3), (11), and the nonnegativity of $N_{\ell-1}$,

$$N_{\ell-1}(t, x) \geq q(t) \frac{\omega(V(t, x))}{K(V(t, x))}$$

(15) for all $(t, x) \in [0, \infty) \times \mathbb{R}^n$. Since $a_1 = -V \geq 0$, our choice of $\Gamma$ and (10) give

$$M_1 = a_2 a_1 - a_2^2 - \Gamma(V) a_1 \leq -N_1 \, , \text{ and}$$

$$M_j \leq - \sum_{m=1}^j a_m^2 + \sum_{m=2}^j a_m |a_m| + |a_3| a_1 - \Gamma(V) a_1$$

$$\leq - \sum_{m=1}^j a_m^2 + \sum_{m=2}^j a_m |a_m| + |a_3| a_1 - [(l + 1) |a_3| + 1 |a_1| a_1 \forall \ j \in \{2, \ldots, \ell - 1\}$$

(16)

It follows from the Cauchy Inequality that for all $j \in \{2, \ldots, \ell - 1\}$,

$$M_j \leq - \sum_{m=1}^j a_m^2 + \Gamma(V) \sqrt{\sum_{m=2}^j a_m^2} - [(l + 1) |a_3| + 1 |a_1| a_1 \leq -N_j + \Gamma(V) \sqrt{N_j}$$

(17)

since $a_1 = -V \geq 0$ everywhere. Also,

$$\dot{S}_1 = \sum_{p=1}^{\ell-1} k_p(V) \dot{M}_p + [k_0(V) + k_0'(V)V] \dot{V}$$

$$+ \sum_{p=1}^{\ell-1} k_p'(V) M_p \dot{V}$$

$$\leq \sum_{p=1}^{\ell-1} k_p(V) \dot{M}_p + [k_0(V) + k_0'(V)V] \dot{V}$$

$$\left[ \sum_{p=1}^{\ell-1} k_p'(V) |M_p| \right] \dot{V}$$

$$\leq \sum_{p=1}^{\ell-1} k_p(V) \dot{M}_p$$

(18)

using (13) and the fact that $\dot{V}$ is nonpositive. Using (16)-(18), we deduce that

$$\dot{S}_1 \leq -k_1(V) N_1$$

$$+ \sum_{p=2}^{\ell-1} k_p(V) \left[ -N_p + \Gamma(V) \sqrt{N_{p-1}} \right]$$

$$\leq - \sum_{p=1}^{\ell-1} k_p(V) N_p + \sum_{p=2}^{\ell-1} k_p(V) \Gamma(V) \sqrt{N_{p-1}}$$

(19)

It follows from (15) that

$$\dot{S}_1 \leq -k_{\ell-1}(V) q(t) \frac{\omega(V)}{K(V)} - \sum_{p=1}^{\ell-2} k_p(V) N_p$$

$$+ \sum_{p=2}^{\ell-1} k_{p+1}(V) \Gamma(V) \sqrt{N_{p-1}}$$

$$\left[ \sum_{p=1}^{\ell-1} L_{1x} q(t) d r ds \leq T^2 \right.$$ and

$$\frac{d}{dt} \int_{t-T}^{t} q(r) d r ds = T q(t) - \int_{t-T}^{t} q(r) d r ds \right.$$

$$\int_{t-T}^{t} q(r) d r ds \leq T^2$$

$$\frac{d}{dt} \int_{t-T}^{t} q(r) d r ds = T q(t) - \int_{t-T}^{t} q(r) d r ds \right.$$}

$$\frac{d}{dt} \int_{t-T}^{t} q(r) d r ds = T q(t) - \int_{t-T}^{t} q(r) d r ds \right.$$
VI. PROOF OF THEOREM 2

In the following proof, we omit the dependencies of the functions on \( x \) when they are clear from the context. To simplify our notation, we introduce the functions

\[
N_i(x) = R(x) \sum_{i=1}^{m} h_i^2(x) \quad \text{and} \\
N_i(x) = \sum_{i=1}^{m} \left[ L_i^{i-1} h_i(x) \right]^2 \quad \forall i \geq 2,
\]

(24)

where \( R(x) = \prod_{i=1}^{m} r_i(x) \div \prod_{i=1}^{m} [r_i(x) + 1] \).

Since \( R \) is everywhere positive and satisfies \( R(x) \leq r_i(x) \) for all \( x \in \mathbb{R}^n \) and all \( i \in \{1, \ldots, m\} \), (6) and our choices (9) of the \( V_i \)'s give

\[
\nabla V_i(x) f(x) \leq -N_i \quad \forall x \in X, \quad \text{and} \\
\nabla V_i(x) f(x) = -\sum_{i=1}^{m} \left[ L_i^{i-1} h_i \right]^2 - \sum_{i=1}^{m} L_i^{i-2} h_i L_i^i h_i \leq -N_i + \sum_{i=1}^{m} |L_i^{i-2} h_i||L_i^i h_i|
\]

for \( i = 2, \ldots, N \) and all \( x \in X \). In particular, we have

\[
\nabla V_2(x) f(x) \leq -N_2 + \sqrt{N_1(x)} \sum_{i=1}^{m} \frac{|L_i^{i-1} h_i|}{\sqrt{R(x)}}, \\
\nabla V_i(x) f(x) \leq -N_i + \sqrt{N_{i-1}(x)} \sum_{i=1}^{m} |L_i^i h_i|
\]

for \( i = 3, 4, \ldots, N \). Our assumptions on \( f \), \( V_1 \), and the \( h_i \)'s allow us to determine a function \( \alpha \in \mathcal{K}_\infty \) such that \( V_i(x) \geq \alpha(|x|) \) for all \( x \in X \), and a continuous everywhere positive function \( \phi \) such that

\[
\sum_{i=1}^{m} \frac{|L_i^i h_i(x)|}{\sqrt{R(x)}} \leq \phi(V_1(x)) \sqrt{V_1(x)} \quad \text{and} \\
\sum_{i=1}^{m} |L_i^i h_i(x)| \leq \phi(V_1(x)) \sqrt{V_1(x)}
\]

(25)

for all \( i \in \{3, \ldots, N\} \) and all \( x \in X \); see Appendix B. It follows that for all \( i \geq 2 \) and \( x \in X \),

\[
\nabla V_i(x) f(x) \leq -N_i + \phi(V_1(x)) \sqrt{N_{i-1}(x)} \sqrt{V_1(x)}.
\]

(26)

Arguing as we did to get (25) gives an increasing everywhere nonnegative function \( p_1 \in C^1 \) such that \( |V_i(x)| \leq p_1(V_i(x)) V_i(x) \) for \( i = 1, \ldots, N \) for all \( x \in X \) (by first finding an increasing positive function \( \alpha \) so that \( V_i(x) \leq \alpha(|x|)|x|^2 \) for all \( i \geq 2 \) and all \( x \) near 0, using the fact that \( h_r(0) = 0 \) for all \( r \) to handle the \( i = 2 \) case). Finally, we can find a decreasing everywhere positive function \( \rho \) so that \( R(x) \geq \rho(\alpha(|x|)) \geq \rho(V_1(x)) \) on \( X \), and then a continuous everywhere positive function \( \rho \) so that

\[
\sum_{i=1}^{N} N_i(x) \geq \rho(V_1(x)) V_1(x)
\]

on \( X \), by (6). Hence, the assumptions of [14, Theorem 1] hold with \( a_i \equiv \frac{1}{2} \), so [14, Theorem 1] constructs the necessary strict Lyapunov-like function.

Remark 3: As we noted above, the results of [14] do not provide general methods for building the auxiliary functions from the Matrosov conditions. Therefore, the novelty of the preceding proof lies in its general procedure for producing the functions \( V_i \) that satisfy the Matrosov conditions. On the other hand, given the functions \( V_i \), \( \phi \), \( p_1 \), and \( \rho \) we constructed above, the results of [14] readily produce the desired strict Lyapunov function \( S \). The strict Lyapunov function takes the form

\[
S(x) = \Omega_1(2V_1(x)) + \sum_{i=2}^{N} \Omega_i(U_i(x))
\]

(27)

where

\[
U_i(x) = V_i(x) + V_1(x)[1 + p_1(V_1(x))]
\]

(28)

for all \( i \geq 2 \), and where the functions \( \Omega_i \in \mathcal{K}_\infty \cap C^1 \) are recursively chosen as follows. We take \( \Omega_N(r) = r \), and then choose \( \Omega_i \) for \( i = 1, 2, \ldots, N-1 \) to satisfy

\[
\Omega_i(U_i) \geq (N-1)^2 \frac{\Delta_1^2(V_1)}{\rho(V_1)} \sum_{r=1+i}^{N} \Omega_r(U_r)^2,
\]

(29)

with \( \Omega_i : [0, \infty) \to [1, \infty) \) continuous and increasing for each \( i \). The formula (27) is the special case of the construction from [14, Theorem 1] when all of the exponents \( a_i \) in [14] are \( \frac{1}{2} \).

Remark 4: A standard “smoothing of the corners” argument that is analogous to the one used to prove [4, Lemma 2.5] allows us to majorize (resp., minorize) any continuous increasing (resp., decreasing) function \( \phi : [0, \infty) \to (0, \infty) \) by a \( C^\infty \) everywhere positive increasing (resp., decreasing) function. Therefore, when \( f \) and \( V_1 \) are both \( C^\infty \), we can use the argument from [14, Theorem 1] in conjunction with smoothing of the corners to guarantee that the functions \( \Omega_i \) are \( C^\infty \), hence a \( C^\infty \) strict Lyapunov function that is consistent with the known converse Lyapunov function theory.

Remark 5: We can prove an analog of Theorem 2 for (1), under a periodic time varying version of Assumption 1. The periodic time varying analog of Assumption 1 is obtained by (A) replacing the arguments of \( f \) and the \( V_i \)'s by \( (t, x) \) and (B) replacing \( \nabla V_i(x) f(x) \) with \( \frac{\partial}{\partial t} \phi(t, x) + \frac{\partial}{\partial x} \phi(t, x) f(x) \).

The proof is then as before, using the periodic time varying extension in [14, Section IV].

VII. ILLUSTRATIONS

A. Periodic Time Varying System

To illustrate Theorem 1 in a reasonably simple way, we take the periodic time varying system

\[
\begin{align*}
\dot{x}_1 &= \cos(t) x_2 \\
\dot{x}_2 &= -\cos(t) x_1 - x_2
\end{align*}
\]

(30)

Along the trajectories of (30), the nonstrict Lyapunov function \( V(x) = \frac{1}{2} |x|^2 \) gives \( \dot{V} = -x_2^2 \). Using the notation from Theorem 1, we get \( a_1(t, x) = x_2^2 \), so \( a_1 = -2 \cos(t) x_1 x_2 - 2x_2^2 \). This gives

\[
a_2(t, x) = -2 \cos(t) x_1 x_2 + 2x_2^2, \quad \text{hence} \quad \dot{a}_2 = -2 \cos^2(t) x_1^2 - 2(3 \cos(t) + \sin(t)) x_1 + (1 + \sin^2(t)) x_2.
\]

Therefore,

\[
a_3(t, x) = 2 \cos^2(t) x_1^2 + 2 [3 \cos(t) + \sin(t)] x_1 + (1 + \sin^2(t)) x_2.
\]
Using the relations $2p^2 + 2q^2 \geq (p + q)^2 \geq \frac{p^2}{16} + \frac{q^2}{16}$ for any $p \geq 0$ and $q \geq 0$ gives
\begin{equation}
\begin{aligned}
a_2^2(t, x) &\geq \frac{1}{2} \cos^2(t) x_1^2 - \frac{1}{4} \cdot \{3 \cos(t) + \sin(t)\} x_1 \\
&\quad + \{1 + \sin^2(t)\} x_2^2 \\
&\geq \frac{1}{2} \cos^2(t) x_1^2 - \frac{1}{4} \cdot \{\|x_1\|^2 + \|x_2\|^2\} \\
&\geq \frac{1}{2} \cos^2(t) x_1^2 - 29V(x) a_1(t, x),
\end{aligned}
\end{equation}

hence
\begin{equation}
\begin{aligned}
\frac{1}{20} \frac{1}{V(x) + 1} a_2^2(t, x) &\geq \frac{1}{100} \frac{1}{V(x) + 1} \cos^2(t) x_1^2 - \frac{3}{4} a_1(t, x).
\end{aligned}
\end{equation}

Noticing that $\frac{1}{20} \frac{1}{V(x) + 1} < 1$ and $V^2(x) \leq \frac{1}{2} (x_1^4 + x_2^4)$, we deduce from (31)-(32) that
\begin{equation}
\begin{aligned}
a_1(t, x) + a_2^2(t, x) + a_3^2(t, x) &\geq \frac{1}{100} \frac{1}{V(x) + 1} \cos^2(t) x_1^2 + \frac{1}{4} a_1(t, x) \\
&\geq \frac{1}{100} \frac{1}{V(x) + 1} \{x_1^4 + x_2^4\} \\
&\geq \frac{1}{200} \frac{1}{V(x) + 1} V^2(x).
\end{aligned}
\end{equation}

Since $4 \cos^2(t) \geq 1$ on $[0, \pi/4]$, we can satisfy the assumptions of Theorem 1 with $V(x) = \frac{1}{4} |x|^2$, $\ell = 3$, $T = 2\pi$, $\tau = \frac{T}{2}$, and $\rho(r) = r^2$/$\{200(r + 1)\}$. See Appendix C for the construction of the strict Lyapunov function $V_2$ that follows the proof of Theorem 1.

B. Lotka-Volterra Example

We illustrate Theorem 2 using the celebrated Lotka-Volterra Predator-Prey system
\begin{equation}
\begin{aligned}
\dot{\chi} &= \gamma \chi (1 - \frac{\chi}{\Delta}) - \alpha \chi \zeta \\
\dot{\zeta} &= \beta \chi \zeta - \Delta \zeta
\end{aligned}
\end{equation}

with positive constants $\alpha$, $\beta$, $\gamma$, $\Delta$, and $L$. System (33) is a simple model of one predator feeding on one prey. The population of the predator is $\zeta$, $\chi$ is the population of the prey, and the constants are related to the birth and death rates; see [6], [11] for an extensive analysis of this model and generalizations to several predators. We assume that the population levels are positive. While there are many Lyapunov constructions for Lotka-Volterra models available (based on computing the LaSalle invariant set), to the best of our knowledge, the result to follow is original and significant because we provide a global strict Lyapunov function.

1) Global Strict Lyapunov Function Construction: The time scaling, change of coordinates, and constants
\begin{equation}
\begin{aligned}
x(t) &= \frac{\chi}{\gamma} \left(\frac{\chi}{\Delta}\right), \\
y(t) &= \frac{\chi}{\Delta} \zeta \left(\frac{\chi}{\Delta}\right),
\end{aligned}
\end{equation}

\begin{equation}
\alpha = \frac{\alpha L}{\gamma} 	ext{ and } d = \frac{\Delta}{\gamma}
\end{equation}
give the simpler system
\begin{equation}
\begin{aligned}
\dot{x} &= x(1 - x) - \alpha xy \\
\dot{y} &= \alpha xy - dy.
\end{aligned}
\end{equation}

We assume that we have imposed assumptions on the parameters such that $\alpha > d$. Let
\begin{equation}
x_* = \frac{2}{\alpha} 	ext{ and } y_* = \frac{1}{\alpha} - \frac{d}{\alpha}. \tag{36}
\end{equation}

Then $x_* \in (0, 1)$ and $y_* > 0$. Also, the new variables $\tilde{x} = x - x_*$ and $\tilde{y} = y - y_*$ have the dynamics
\begin{equation}
\begin{aligned}
\dot{\tilde{x}} &= -\tilde{x} + \alpha \tilde{y} \tilde{x} + x_* \\
\dot{\tilde{y}} &= \alpha \tilde{x} (\tilde{y} + y_*),
\end{aligned}
\end{equation}

with state space
\begin{equation}
\mathcal{X} = (-x_*, +\infty) \times (-y_*, +\infty).
\end{equation}

We do our Lyapunov function construction for (37), so we set
\begin{equation}
\begin{aligned}
f_2(\tilde{x}, \tilde{y}) &= \left(\frac{1}{\alpha} \tilde{x} + \tilde{y}\right)^2 (\tilde{x} + x_*) \\
&= \frac{1}{\alpha} \tilde{x} + \tilde{y} + \frac{\alpha}{y_* + y} \tilde{x} + y_*.
\end{aligned}
\end{equation}

We verify Assumption 1 with
\begin{equation}
\begin{aligned}
m &= 1, \\
N &= 2, \\
r_1 &= 1, \\
h_1(\tilde{x}, \tilde{y}) &= \tilde{x}, \\
V_1(\tilde{x}, \tilde{y}) &= \tilde{x} - x_* \ln \left(1 + \frac{\tilde{x}}{x_*}\right) + \tilde{y} - y_* \ln \left(1 + \frac{\tilde{y}}{y_*}\right).
\end{aligned}
\end{equation}

One easily checks that $V_1$ is a (time invariant) storage function. Along the trajectories of (37),
\begin{equation}
\begin{aligned}
\dot{V}_1 &= -\tilde{x} + \alpha \tilde{y} \tilde{x} + \frac{\alpha}{y_* + y} \tilde{x} + y_* \\
&= -\tilde{x} + \alpha \tilde{y} + \alpha \tilde{x} \tilde{y} = -\tilde{x}^2.
\end{aligned}
\end{equation}

Also, $L h_1(\tilde{x}, \tilde{y}) = -[\tilde{x} + \alpha \tilde{y}] (\tilde{x} + x_*)$. One can check that $V_1$ has a positive definite quadratic lower bound near the origin; see Appendix D. A simple argument provides a positive constant $d$ such that
\begin{equation}
\begin{aligned}
\frac{1}{2} h_1^2(\tilde{x}, \tilde{y}) + [L h_1(\tilde{x}, \tilde{y})]^2 \geq \frac{d}{1 + V_1(\tilde{x}, \tilde{y})}
\end{aligned}
\end{equation}
on $\mathcal{X}$; see Appendix E. Hence, Assumption 1 holds with
\begin{equation}
\rho(r) = \frac{d}{1 + r^2}; \tag{42}
\end{equation}
so Theorem 2 constructs the necessary global strict Lyapunov function for (37).

We construct the strict Lyapunov function from Theorem 2. Set
\begin{equation}
N_1(\tilde{x}, \tilde{y}) = \frac{1}{2} h_1^2(\tilde{x}, \tilde{y}) \text{ and } N_2(\tilde{x}, \tilde{y}) = [L h_1(\tilde{x}, \tilde{y})]^2.
\end{equation}

Notice that
\begin{equation}
\begin{aligned}
L h_1(\tilde{x}, \tilde{y}) &= -(x_* + 2\tilde{x} + \alpha \tilde{y}) \tilde{x} - (x_* + \tilde{x}) \alpha \tilde{y}.
\end{aligned}
\end{equation}

Therefore,
\begin{equation}
\begin{aligned}
\left|h_1(\tilde{x}, \tilde{y})\right| &\leq (2 + \alpha + x_*)^2 (1 + |\tilde{x}| + |\tilde{y}|)^2 (|\tilde{x}| + |\tilde{y}|) \\
&\quad + \alpha^2 (1 + x_* + y_*^2) (1 + |\tilde{x}|) (1 + |\tilde{y}|) |\tilde{x}|.
\end{aligned}
\end{equation}

On the other hand, Appendix D applied with $A = \tilde{x}/x_*$ gives
\begin{equation}
\begin{aligned}
\left|\frac{\tilde{x}}{x_*}\right| &\leq 2 \left\{\frac{V_1 + V_2}{x_*^2}\right\}^{1/2} \\
&\leq 2 \max\left\{\frac{1}{x_*^2}, \frac{1}{x_*^4}\right\} \left\{V_1 + V_2\right\}^{1/2}
\end{aligned}
\end{equation}
and similarly for $y$, so
\begin{equation}
\begin{aligned}
\max\{|\tilde{x}|, |\tilde{y}|\} &\leq J(V_1) \sqrt{V_1}, \\
\text{where } J(V_1) &= (2(1 + x_* + y_*) \sqrt{V_1} + 1.
\end{aligned}
\end{equation}
Combining (44) and (46) gives
\[ |L_2^2 h_1(\tilde{x}, \tilde{y})| \leq \left\{ 2J(V_1)(2 + \alpha + x_*)^3 \left[ 1 + 2J(V_1)\sqrt{\frac{1}{V_1}} \right]^2 + \alpha^2(1 + x_* + y_*)^2 J(V_1)(1 + J(V_1)\sqrt{\frac{1}{V_1}})^2 \right\} \sqrt{\frac{1}{V_1}}. \] (47)
Therefore, we can satisfy (25)-(26) with \( p_1(r) = 4(1 + \alpha^2)(3 + \alpha + y_*)^3 (1 + 2J(r)\sqrt{\frac{1}{T^2}}) J(r) \).

Since \( V_2(\tilde{x}, \tilde{y}) = \tilde{x}^2 + \alpha\tilde{y}\), we easily get
\[ |V_2(\tilde{x}, \tilde{y})| \leq 2(\tilde{x}^2 + 1)(1 + \alpha)(\tilde{y}^2 + x^2 + \tilde{y}^2). \] (48)
Combining (46) and (48) and setting \( \tilde{d} = 1 + x_* + y_* \), simple algebra gives
\[ |V_2(\tilde{x}, \tilde{y})| \leq 4(\tilde{x}^2 + 1)(1 + \alpha) \sum_{i=2}^2 \left\{ 2\tilde{d}^i \sqrt{\frac{1}{V_1}} \right\} \leq p_1(V_1(\tilde{x}, \tilde{y})) V_1(\tilde{x}, \tilde{y}), \]
where \( p_1(r) = 640(\tilde{x}^2 + 1)(1 + \alpha)2^3(1 + r)^3 \). Since we also have\[
\sum_{i=1}^2 \mathcal{N}_i(\tilde{x}, \tilde{y}) \geq \tilde{\rho}(V_1(\tilde{x}, \tilde{y})) V_1(\tilde{x}, \tilde{y}), \]
and since
\[ U_2(\tilde{x}, \tilde{y}) = V_2(\tilde{x}, \tilde{y}) + \left[ p_1(V_1(\tilde{x}, \tilde{y})) + 1 \right] V_1(\tilde{x}, \tilde{y}) \geq V_1(\tilde{x}, \tilde{y}) \]
everywhere, it follows from (27)-(29) that the desired strict Lyapunov-like function we get is
\[ S(\tilde{x}, \tilde{y}) = V_2(\tilde{x}, \tilde{y}) + \left[ p_1(V_1(\tilde{x}, \tilde{y})) + 1 \right] V_1(\tilde{x}, \tilde{y}) \]
\[ + \frac{8}{2} \int_0^{(\tilde{x}, \tilde{y})} \left( 1 + x^2 \right) \phi_r^2(r) \mathrm{d}r. \] (49)
Moreover, \( S(\tilde{x}, \tilde{y}) \) is a strict Lyapunov function because \( V_1(\tilde{x}, \tilde{y}) \) goes to infinity when \( \tilde{x} \) goes to \(-\infty\) or \(+\infty\), or when \( \tilde{y} \) goes to \(-\infty\) or \(+\infty\).

**Remark 6:** Due to its restricted state space, it is not possible to apply Theorem 1 to the Lotka-Volterra example directly. However, a change of variables that transforms the state space to all of Euclidean space makes it possible to apply to Theorem 1. See Appendix F for details.

2) **ISS and iISS:** We can use our strict Lyapunov function constructions to quantify the effects of uncertainty in the Lotka-Volterra dynamics. We illustrate this by showing that the dynamics are (i)ISS with respect to additive uncertainty in the death rate \( \Delta \) for the predator. Using the coordinate change and constants (34), this means that we replace the constant \( d > 0 \)
with \( d + u \) in the dynamics (35), where \( u : [0, \infty) \to \mathbb{R} \) is a measurable essentially bounded uncertainty, and where \( d \) now represents the nominal (or estimated) value of the parameter. Later, we impose a bound on the allowable values for \( |u|_{\infty} \).

We continue to use \( d \) in the formulas (36) for \( x_* \) and \( y_* \); we do not introduce uncertainty in the equilibrium values. Set \( \delta_B_r = \{ x \in \mathbb{R}^r : |x| \leq \delta \} \) for any constants \( r \in \mathbb{N} \) and \( \delta > 0 \).

We first define an appropriately restricted state space. Along the trajectories of (35), with \( d \) replaced by \( d + u \), we have \( \dot{x} + \dot{y} = x(1 - x) - (d + u)y \). Hence, if \( |u|_{\infty} \leq d/2 \) with \((x, y) \in (0, \infty)^2 \), then \( \dot{x} + \dot{y} < 0 \) when \( x + y > 1 + \frac{d}{2} \) (by separately considering the cases \( x > 1 \) and \( x \leq 1 \)). Therefore, we restrict to disturbances satisfying \( |u|_{\infty} \leq d/2 \) and the forward invariant set
\[ S = \{ (x, y) \in (0, \infty)^2 : x + y \leq B \}, \]
where \( B = 1 + \frac{d}{2} + y_* \),
we added \( y_* \) to ensure that \((x, y_*), u \) is. The corresponding perturbed error dynamics
\[ \begin{align*}
\dot{x} &= -[\tilde{x} + \alpha\tilde{y}](\tilde{x} + x_*), \\
\dot{y} &= \alpha\tilde{x}(\tilde{y} + y_*) - uy, 
\end{align*} \] (51)
has the state space \( \chi^\theta = \{ (\tilde{x}, \tilde{y}) : (x, y) \in S \} \) and a control set \( U \) we will specify. Our strategy is to build an appropriate strict Lyapunov function for (51) for the special case where \( u \equiv 0 \) (i.e., (37)), which we then use to prove ISS of (51) with respect to the uncertainty \( u \).

To account for the restricted state space of the system, we use the following definitions. Given an open subset \( D \) of a Euclidean space that contains the origin, we say that a positive definite function \( \bar{\alpha} : D \to [0, \infty) \) is a modulus with respect to \( D \) provided \( \bar{\alpha}(p) \to \infty \) as \( |p| \to \infty \) or as \( \text{dist}(p, \partial D) \to 0 \) (with \( p \) remaining in \( D \)). We say that (51) is ISS with respect to \( u \) provided there exist functions \( \beta \in KL \) and \( \gamma \in K_{\infty} \), and a modulus with respect to \((-\infty, \infty) \times (-\infty, \infty) \), such that for each disturbance \( u : [0, \infty) \to U \) and each trajectory \((\tilde{x}, \tilde{y}) : [0, \infty) \to \chi^\theta \) of (51) corresponding to \( u \), we have
\[ \sup_{t \geq 0} |(\tilde{x}(t), \tilde{y}(t))| \leq \beta \left( \bar{\alpha}((\tilde{x}(0), \tilde{y}(0)), t) \right) + \gamma(|u|_{\infty}) \quad \forall t \geq 0. \] (52)
To simplify the statements of our results, we use the constants
\[ K_0 = 2 \left[ \frac{(3 + \alpha^2)^2}{2} + \alpha^2 \right] B^2, \]
\[ K = B^2 \max \left\{ (3 + \alpha^2)^2 + 2\alpha^2, 2\max\{9, 3\alpha^2\} \right\}, \]
\[ K = \min \left\{ 32x_*, x_*^2\alpha^2 y_* \right\}, \]
\[ \bar{U} = \min \left\{ \frac{K_0 x_*^2 y_*^2 \alpha^2}{8}, \frac{K_0 x_*^2 y_*^2 \alpha^2}{8 (x_* + 2\sqrt{K_0})^2} \right\}, \]
and \( \theta = \min \left\{ \frac{K_0 x_*^2 y_*^2 \alpha^2}{8}, \frac{K_0 x_*^2 y_*^2 \alpha^2}{8 (x_* + 2\sqrt{K_0})^2} \right\}, \]
where \( B \) is from (50). We continue to use the functions \( V_1 \) and \( V_2 \) from the preceding subsection. We prove the following (but see Remark 7 for integral ISS results under a less stringent disturbance bound, and Section VII-B3 for a specific numerical example):

**Theorem 3:** The system (51) is ISS with respect to disturbances \( u \) valued in \( \bar{U} \).

**Proof:** The time derivatives of the functions \( V_1 \) and \( V_2 \) defined in Section VII-B, along the trajectories of (51) in \( \chi^\theta \), satisfy
\[ \dot{V}_1 = -\bar{x}^2 - \bar{y}^2 \leq -\bar{x}^2 + B|u| \]
and
\[ \dot{V}_2 = -(\bar{x} + \alpha\bar{y})^2 \bar{x}^2 \]
\[ + \{ -\bar{x}(2\bar{x} + x_*) - \alpha\bar{y}\bar{x} \} (\bar{x} + \alpha\bar{y})x \]
\[ + \bar{x}^2 \alpha^2 \bar{x} - \alpha\bar{y}\bar{x} \]
\[ \leq -\frac{1}{2} (\bar{x} + \alpha\bar{y})^2 \bar{x}^2 + \frac{1}{2} (\bar{x}(2\bar{x} + x_*) + \alpha\bar{y}\bar{x})^2 \]
\[ + \alpha^2 \bar{x}^2 \bar{y} \alpha - \alpha\bar{x} \bar{u} \bar{x} \bar{y}, \] (54)
by the triangle inequality. Since \((x, y) \in \mathcal{S}\), we deduce that
\[
\dot{V}_2 \leq \frac{1}{2} (\bar{x} + \alpha \bar{y})^2 \bar{x}^2 + \frac{3(\alpha + 2)x + 2}{2} \bar{x}^2 \\
+ \alpha \bar{x}^2 + \alpha B |u| B^2 \\
\leq \frac{1}{2} (\bar{x} + \alpha \bar{y})^2 \bar{x}^2 + \frac{3(\alpha + 2)x + 2}{2} B^2 \bar{x}^2 \\
+ \alpha B |u| B^2 \\
(55)
\]
where \(K = K + B^2 \max \{9, 3\alpha^2\}\). Also, the inequality \(x \geq \frac{\bar{x}}{2}\) from (61) implies that
\[
Q(\bar{x}, \bar{y}) \geq \frac{x^2}{2} (\bar{x} + \alpha \bar{y}) + \frac{K_0}{2} \bar{x}^2 \\
(66)
\]
By separately considering the possibilities \(|\bar{x}| \geq \frac{1}{\alpha} |\bar{y}|\) and \(|\bar{x}| \leq \frac{1}{\alpha} |\bar{y}|\) and noting that \(K_0 \geq 9B^2 \geq 9\), it follows from (66) that
\[
Q(\bar{x}, \bar{y}) \geq \frac{x^2}{16} \alpha^2 \bar{y}^2 + 2 \bar{x}^2 \\
\geq \min \left\{ \frac{x^2}{16} \alpha^2 \bar{y}^2, 2x \right\} \left[ \frac{x^2}{\alpha^2} + \frac{\bar{y}^2}{\bar{y}^2} \right] .
(67)
Combining (65) and (67) yields
\[
\dot{U}_K(\bar{x}, \bar{y}) \leq K \min \left\{ \frac{x^2}{\alpha^2} + \frac{\bar{y}^2}{\bar{y}^2} \right\} \\
(68)
\]
Recalling the estimate \(\dot{U}_K \leq -Q(\bar{x}, \bar{y}) + \overline{B} |u|\), we deduce that
\[
\dot{U}_K \leq -\Theta \dot{U}_K(\bar{x}, \bar{y}) + \overline{B} |u| \\
(69)
\]
where \(\Theta = \min \{K, \theta\}\). Let \(\dot{U}_K(\bar{x}, \bar{y}) = U_K(\bar{x}, \bar{y}) e^{\dot{U}_K(\bar{x}, \bar{y})}\).
Then
\[
\dot{U}_K = e^{\dot{U}_K(\bar{x}, \bar{y})} \left[ 1 + U_K(\bar{x}, \bar{y}) \right] \dot{U}_K \\
\leq e^{\dot{U}_K(\bar{x}, \bar{y})} \left\{ -\Theta \overline{B} |u| \right\} \dot{U}_K(\bar{x}, \bar{y}) + \overline{B} |u| .
\]
Therefore, when \(|u|_\infty \leq \frac{\alpha}{2\sqrt{2}}\), we have
\[
\dot{U}_K \leq e^{\dot{U}_K(\bar{x}, \bar{y})} \left[ -\frac{\alpha}{2\sqrt{2}} U_K(\bar{x}, \bar{y}) + \overline{B} |u| \right] \\
\leq -\frac{\alpha}{2\sqrt{2}} U_K(\bar{x}, \bar{y}) + \overline{B} |u| e^{\dot{U}_K(\bar{x}, \bar{y})} \\
\leq -\frac{\alpha}{2\sqrt{2}} U_K(\bar{x}, \bar{y}) + \overline{B} |u| \left[ e^{\dot{U}_K(\bar{x}, \bar{y})} - 1 \right] \\
+ \overline{B} |u| \\
\leq -\frac{\alpha}{2\sqrt{2}} U_K + \overline{B} |u| U_K + \overline{B} |u| \\
\]
where the last inequality used the condition \(e^{\alpha} - 1 \leq \alpha e^{\alpha}\) for all \(\alpha \geq 0\). Therefore, when \(\overline{B} |u| \leq \frac{\alpha}{4}\), we obtain
\[
\dot{U}_K \leq -\frac{\alpha}{4} U_K(\bar{x}, \bar{y}) + \overline{B} |u| .
(71)
\]
The desired ISS inequality (52) now follows from a slight variant of the standard arguments [20].

Remark 7: The Lyapunov function construction in the preceding proof can be used to explicitly construct the functions \(\beta, \gamma\), and \(\alpha\) in the ISS estimate (52). The inequality (69) implies that \(U_K\) is an iISS Lyapunov function for the Lotka-Volterra errors dynamics (51) when the disturbance \(u\) satisfies the less stringent bound \(|u|_\infty \leq \frac{\alpha}{4}\); see [20] for the original treatment of iISS, and see [2], [3], [21] for extensive iISS discussions and results. In fact, a slight variant of the iISS arguments from [3] in conjunction with (69) and the growth properties of \(U_K\) can be used to explicitly construct functions.
\( \beta \in KL \) and \( \gamma \in K_{\infty} \), a constant \( \tilde{G} > 0 \), and a modulus \( \tilde{\alpha} \) with respect to \((-x_*, \infty) \times (-y_*, \infty)\), such that for each disturbance \( u : [0, \infty) \to [-d/2, d/2] \) and each trajectory \((\tilde{x}, \tilde{y}) : [0, \infty) \to \mathbb{R}^2\) of (51) corresponding to \( u \), we have
\[
\gamma(|(\tilde{x}, \tilde{y})(t)|) \leq \beta \left( \tilde{\alpha}((\tilde{x}, \tilde{y})(0)), t \right) + \tilde{G} \int_0^t |u(r)|dr \forall t \geq 0. \quad (72)
\]

We next illustrate these ideas in simulations.

3) Simulations: To illustrate our findings, we simulated the dynamics (51) using the parameter values \( \alpha = 2, \ d = 1, \ x_* = 0.5, \) and \( y_* = 0.25 \), corresponding to the parameter choices
\[
a = \gamma = \beta = \Delta = 0.5 \quad \text{and} \quad L = 2 \quad (73)
\]
in the original model. Hence, (51) is iISS with respect to disturbances that are bounded by 0.5. We chose the disturbance \( u(t) = 0.49e^{-t} \). In Figures 1-2, we plotted the corresponding levels of \( \zeta \) and \( \chi \), which are related to \( x \) and \( y \) in terms of the coordinate changes (34).

![Population of Predator](image1)

Fig. 1. Population of Predator \( \zeta \) in Lotka-Volterra Dynamics (51) with Parameters (73) and \( u(t) = 0.49e^{-t} \)

![Population of Prey](image2)

Fig. 2. Population of Prey \( \chi \) in Lotka-Volterra Dynamics (51) with Parameters (73) and \( u(t) = 0.49e^{-t} \)

If \( x(t) \to x_* = 0.5 \) and \( y(t) \to y_* = 0.25 \), then the coordinate changes (34) give
\[
\zeta(t) \to 0.25 \frac{\beta L}{a} = 0.5 \quad \text{and} \quad \chi(t) \to 0.5L = 1, \quad (74)
\]
which is what we see in the figures. This shows the robustness of the convergence in the face of the disturbance \( u \).

VIII. Conclusion

We gave new methods for building global strict Lyapunov functions under LaSalle conditions. The novelty of our first result is in the generality of its assumptions. The novelty of our second is in the local properties of our strict Lyapunov functions and its applicability on general state spaces. As a byproduct, we exhibited a general class of auxiliary functions for which the Matrosov theorem from [14] applies. We illustrated our work using a robustness analysis for the Lotka-Volterra model.

Appendix A

A Useful Lower Bound

We used the following simple lemma in Section V:

**Lemma A.1:** For each continuous positive definite function \( \rho : [0, \infty) \to [0, \infty) \), we can find a function \( \omega \in K_{\infty} \cap C^1 \) and a strictly increasing everywhere positive function \( K \in C^1 \) such that
\[
\rho(r) \geq \frac{\omega(r)}{K(r)} \quad (A.1)
\]
for all \( r \geq 0 \).

**Proof:** By replacing \( \rho \) with
\[
\rho_{\text{new}}(r) = \begin{cases} r \min\{\rho(q) : r \leq q \leq 1\}, & 0 \leq r \leq 1 \\ \min\{\rho(q) : 1 \leq q \leq r\}, & r > 1 \end{cases}
\]
without relabeling and noting that \( \rho_{\text{new}}(r) \leq \rho(r) \) for all \( r \geq 0 \), we can assume that \( \rho \) is strictly increasing on \([0, 1]\) and nonincreasing on \([1, \infty)\). Notice that
\[
\rho(r) = \frac{\omega_0(r)}{K_0(r)} \quad (A.2)
\]
for all \( r \geq 0 \), where \( \omega_0 \) and \( K_0 \) are the increasing continuous functions
\[
\omega_0(r) = \begin{cases} \rho(r) / \rho(1), & 0 \leq r \leq 1 \\ r, & r \geq 1 \end{cases} \quad \text{and} \quad K_0(r) = \begin{cases} 1 / \rho(1), & 0 \leq r \leq 1 \\ r, & r \geq 1 \end{cases}. \quad (A.3)
\]
We can then satisfy (A.1) by picking any function \( \omega \in K_{\infty} \cap C^1 \) such that \( \omega(r) \leq \omega_0(r) \) for all \( r \geq 0 \) and any strictly increasing \( C^1 \) function \( K \) such that \( K(r) \geq K_0(r) \) for all \( r \geq 0 \).

Appendix B

Verifying Estimates (25)

We only show the second estimate in (25); the other estimate in (25) is handled similarly. We maintain the notation from Section VI. Since \( f(0) = 0 \), all of the functions \( L_i^+h_i(x) \) are zero at the origin and sufficiently smooth for all \( i \in \mathbb{N} \). Also, Assumption 1 provides a positive definite quadratic lower bound for \( V_1 \) near the origin. Moreover, the fact that \( V_1 \) is a storage function implies that there exists a function \( \underline{\alpha} \in K_{\infty} \) such that \( V_1(x) \geq \underline{\alpha}(|x|) \) for all \( x \in X \). Hence,
\[
\sum_{i=1}^m |L_i^+h_1(x)| \leq |x|G_1(|x|) \leq \tilde{\kappa} \sqrt{V_1(x)G_1(\underline{\alpha}^{-1}(V_1(x)))}
\]
for all $i \in \{3, \ldots, N\}$ for some increasing everywhere positive function $G_i$ and some constant $\bar{k} > 0$ in some neighborhood $\mathcal{O}$ of the origin (by our choice of $\underline{a}$ and the fact that $V_1$ is bounded from below by a positive definite quadratic function near 0). We can also find a $G_2 \in \mathcal{K}_{\infty}$ so that
\[
\sum_{i=1}^{m} \frac{|L_i h(x)|}{\sqrt{\Delta_i(x)}} \leq G_2(|x|) \quad \forall i \in \{3, \ldots, N\}
\]
on $\mathbb{R}^n \setminus \mathcal{O}$. Hence, we can take $\phi_1(r) = 1 + \bar{k}G_1(a^{-1}(r)) + G_2(a^{-1}(r))$.

APPENDIX C

Strict Lyapunov Function for (30)

We construct the functions needed for the strict Lyapunov function construction for (30). We use the notation from Section VII-A and the proof of Theorem 1. Then
\[
\begin{align*}
\dot{a}_3 &= -2\sin(2t)x_1^2 + 2(-3 \sin(t) + \cos(t))x_1x_2 \\
&\quad + 4\cos^3(t)x_1x_2 \\
&\quad + 2(\sin(2t) + \cos(t) |3 \cos(t) + \sin(t)|)x_2^2 \\
&\quad - 2 \left[ (3 \cos(t) + \sin(t))x_1 + 2(1 + \sin^2(t))x_2 \right] \\
&\quad \times \cos(t)x_1 + x_2.
\end{align*}
\]

Applying the relation $|x_1x_2| \leq \frac{3}{2}(x_1^2 + x_2^2)$ and collecting coefficients of $x_1^2$ and $x_2^2$ readily gives $\max \{ |a_i(t, x)| : t \in \mathbb{R}, 1 \leq i \leq 4 \} \leq 64V(x)$, so $\Gamma(r) = 320r + 1$ satisfies our requirements. Since $t \leq 3$, $T = 2\pi$, and $\tau = \frac{\pi}{2}$, taking $\omega(r) = r^2$ and $K(r) = 200(r + 1)$ gives
\[
\begin{align*}
\Omega(r) &= \frac{2v_0(r)}{\Omega(t - 2\pi)(r)(v_{\infty})} \\
&\quad = 2400v_0^2(320v_0 + 1), \\
k_2(r) &= \omega^{2 - 1}(v) = v_8, \\
k_1(v) &= k_2(v) \frac{\theta_{2}(v)}{\theta_{1}(v)} = 2400v_6(320v_6 + 1)^{2}. 
\end{align*}
\]

Since $\omega(v) = v^2$, our requirement (14) on $G$ is satisfied if $G'(v) \geq \frac{2v^2}{K(v)}(k_2(v)2vK(v) - 200v^2) + k_2(v)^2 v^4$ for all $v \geq 0$, which holds if $G(v) = \pi v^5 e^v$.

Since $|M_1(t, x)| = \max |a_1(t, x)|a_2(t, x) + 160V_2(x) + V(x) \leq 172V_2(x) + V(x)$ and $|M_2(t, x)| = \max |a_1(t, x)|a_2(t, x) + 160V_2(x) + V(x) \leq 268V_2(x) + V(x)$, we can satisfy (13) using $k_0(v) = (k^2(v) + k_2(v)^2)(268v^2 + v) + 1$. Also, $|S_2(t, x)| \leq G(v)^{2} + 2v^{10}(x)$ and $|S_1(t, x)| \leq \max(k_0(V(x)) + k_2(V(x)))^2(|268V_2(x) + V(x)| + k_0(V(x)))V(x)$. Therefore, we can take
\[
k(v) = \left[ k_1(v) + k_2(v) \right](268v^2 + v) + k_0(v)v + G(v) + 2v^{10} + 1.
\]
The formula for $V^2$ is now immediate from plugging the preceding functions into (10) from Theorem 1.

APPENDIX D

Useful Inequalities

We used the following simple lemma in Section VII-B:

Lemma A.2: For all $A \in (-\infty, \infty)$, the following inequalities hold:
\[
\begin{align*}
A - \ln(1 + A) &\geq \frac{A^2}{2(1 + |A|)} \quad \text{and} \\
|A| &\leq 2\sqrt{|A - \ln(1 + A)| + (A - \ln(1 + A))^2} .
\end{align*}
\]
so that
\[ \frac{1}{2} \tilde{x}^2 + (\tilde{x} + \alpha \tilde{y})^2 \geq c_\ast (\tilde{x}^2 + \tilde{y}^2) \]
on \mathbb{R}^2, which is bounded below by \( c_\ast y^2_\ast /4 \) when \( \tilde{y} \leq -y_\ast + \delta \).

Hence,
\[
\sum_{i=1}^{2} N_i(\tilde{x}, \tilde{y}) \geq \delta^2 \frac{c_{\ast}}{8} \min \{ x_\ast^2, y_\ast^2 \} =: m(\delta) \quad (A.11)
\]
on \mathcal{D}. Reducing \( \delta > 0 \) and recalling (A.8) guarantees that
\[
\frac{\delta^2 V_1(\tilde{x}, \tilde{y})}{1 + V_1^2(\tilde{x}, \tilde{y})} \leq m(\delta) \quad (A.12)
\]
on \mathcal{D}. The claim now follows by combining (A.11)-(A.12). Fix a constant \( \delta > 0 \) satisfying the preceding requirements.

We next consider points in \( \mathcal{X} \setminus \mathcal{D} \). For each constant \( q > 0 \), we can find a constant \( c(q) > 1 \) such that
\[
E(p, q) \leq c(q)p^2 \quad \forall p \geq -q + \delta,
\]
by applying L'Hôpital's rule to \( E(p, q)/p^2 \) as \( p \to 0 \) or \( p \to \infty \). Therefore,
\[
V_1(\tilde{x}, \tilde{y}) = \tilde{x}^2 \left( \frac{E(\tilde{x}, \tilde{y})}{\tilde{x}^2} \right) + \tilde{y}^2 \left( \frac{E(\tilde{y}, \tilde{y})}{\tilde{y}^2} \right)
\]
\[
\leq \left[ c(x_\ast) + c(y_\ast) \right] (\tilde{x}^2 + \tilde{y}^2)
\]
on \mathcal{X} \setminus \mathcal{D} when neither \( \tilde{x} \) nor \( \tilde{y} \) is zero. Similar reasoning gives
\[
V_1(\tilde{x}, \tilde{y}) \leq \left[ c(x_\ast) + c(y_\ast) \right] (\tilde{x}^2 + \tilde{y}^2)
\]
on all of \( \mathcal{X} \setminus \mathcal{D} \) (by separately considering the possibilities \( \tilde{x} = 0 \) and \( \tilde{x} \neq 0 \) and similarly for \( \tilde{y} \)). Moreover, we can find a constant \( \epsilon > 0 \) so that
\[
N_1(\tilde{x}, \tilde{y}) + N_2(\tilde{x}, \tilde{y}) \geq \epsilon (\tilde{x}^2 + \tilde{y}^2)
\]
on \mathcal{X} \setminus \mathcal{D}, because \( (\tilde{x} + x_\ast)^2 \geq \delta^2 \) on \( \mathcal{X} \setminus \mathcal{D} \) and
\[
\frac{1}{2} \tilde{x}^2 + \delta^2 [\tilde{x} + \alpha \tilde{y}]^2
\]
is a positive definite quadratic function (again using the fact that \( \alpha > 0 \)). Therefore,
\[
\sum_{i=1}^{2} N_i(\tilde{x}, \tilde{y}) \geq \left( \frac{\epsilon}{c(x_\ast) + c(y_\ast)} \right) \left[ c(x_\ast) + c(y_\ast) \right] (\tilde{x}^2 + \tilde{y}^2) \quad (A.13)
\]
on \mathcal{X} \setminus \mathcal{D}. It follows from (A.10) that we can take
\[
d = \min \left\{ \frac{\tilde{x}^2}{c(x_\ast) + c(y_\ast)}, \delta^2 \right\} \quad (A.14)
\]

**Appendix F**

**Strict Lyapunov Function for Lotka-Volterra Dynamics Using Theorem 1**

To further illustrate Theorem 1, we show how it applies to the Lotka-Volterra dynamics, after a change of variables. We take the change of coordinates
\[
\xi = \ln(x) \quad \text{and} \quad \psi = \ln(y).
\]
Taking \( x_\ast = \frac{4}{\alpha} \in (0, 1) \) and \( y_\ast = \frac{1-x_\ast}{\alpha} > 0 \) as before, we also set
\[
\xi_\ast = \ln(x_\ast) \quad \text{and} \quad \psi_\ast = \ln(y_\ast).
\]
This and (35) give
\[
\begin{align*}
\dot{\xi} &= \ x_\ast \left[ 1 - e^{\xi} \right] + \theta_1 \left[ 1 - e^{\psi} \right] \\
\dot{\psi} &= \theta_2 \left[ e^{\xi} - 1 \right]
\end{align*}
\]
for the error variables \( \dot{\xi} = \xi - \xi_\ast \) and \( \dot{\psi} = \psi - \psi_\ast \), where
\[
\theta_1 = \alpha y_\ast \quad \text{and} \quad \theta_2 = \alpha x_\ast.
\]
The state space for (A.15) is \( \mathbb{R}^2 \).

We show how (A.15) is covered by Theorem 1. Due to space constraints, we do not construct the strict Lyapunov function for (A.15) from Theorem 1, since we already constructed the strict Lyapunov function (49) for the Lotka-Volterra error dynamics using Theorem 2. Let
\[
V(\xi, \psi) = \theta_2 \left[ e^{\xi} - 1 - \xi \right] + \theta_1 \left[ e^{\psi} - 1 - \psi \right].
\]
Then \( V \) is a storage function whose time derivative along the trajectories of (A.15) satisfies
\[
\dot{V} = \theta_2 \left[ e^{\xi} - 1 \right] \left[ x_\ast \left( 1 - e^{\xi} \right) + \theta_1 \left( 1 - e^{\psi} \right) \right]
\]
\[
+ \theta_1 \left[ e^{\psi} - 1 \right] \theta_2 \left[ e^{\xi} - 1 \right]
\]
\[
= -\theta_3 \left[ e^{\xi} - 1 \right]^2,
\]
where \( \theta_3 = \theta_2 x_\ast \), so \( V \) is a nonstrict Lyapunov function for the error dynamics (A.15). Also,
\[
a_1 = \theta_3 [e^{\xi} - 1]^2 \geq 0.
\]
Taking \( a_2 = -a_1 \) as before gives
\[
\dot{a}_1 = 2\theta_3 e^{\xi} \left[ -x_\ast \left( 1 - e^{\xi} \right)^2 - \theta_1 \left( e^{\xi} - 1 \right) \left( e^{\psi} - 1 \right) \right],
\]
so
\[
\dot{a}_2 = 2\theta_3 e^{\xi} \xi \left[ x_\ast \left( 1 - e^{\xi} \right)^2 + \theta_1 \left( e^{\xi} - 1 \right) \left( e^{\psi} - 1 \right) \right]
\]
\[
+ 2\theta_3 e^{\xi} \xi \left[ 2x_\ast \left( e^{\xi} - 1 \right) e^{\xi} \xi + \theta_1 \left( e^{\psi} - 1 \right) e^{\xi} \xi \right]
\]
\[
+ \theta_1 \left( e^{\xi} - 1 \right) e^{\psi} \xi.
\]
Therefore,
\[
\begin{align*}
\frac{\partial \dot{V}}{\partial \xi} &= \dot{\xi} \left[ x_\ast \left( 1 - e^{\xi} \right)^2 + \theta_1 \left( e^{\xi} - 1 \right) \left( e^{\psi} - 1 \right) \right]
\]
\[
+ 2x_\ast \left( e^{\xi} - 1 \right) e^{\xi} \xi
\]
\[
+ \theta_1 \left( e^{\psi} - 1 \right) e^{\xi} \xi + \theta_1 \left( e^{\xi} - 1 \right) e^{\psi} \xi
\]
\[
= \dot{\xi} \left[ a_1 + 2x_\ast \left( e^{\xi} - 1 \right) e^{\xi} \xi \right]
\]
\[
+ \theta_1 \left[ e^{\psi} - 1 \right] e^{\xi} \xi \]
\[
+ \theta_1 \left( e^{\psi} - 1 \right) e^{\xi} \xi \left[ x_\ast \left( 1 - e^{\xi} \right) + \theta_1 \left( 1 - e^{\psi} \right) \right]
\]
which gives
\[
\frac{\dot{a}_2}{2\theta_3 e^\xi} = \left[ x_\ast \left(1 - e^\xi\right) + \theta_1 \left(1 - e^\psi\right) \right] \\
\times \left[ a_2 + 2\theta_3 x_\ast \left( e^\xi - 1 \right) e^{2\xi} \right] + 2\theta_2 a_1 e^\xi e^\psi \\
+ \left[ 2\theta_3 x_\ast \theta_1 e^{2\xi} \left( e^\psi - 1 \right) \left(1 - e^\xi\right) \right] \\
- \theta_2 e^\xi \left( e^\psi - 1 \right) \left(1 - e^\xi\right).
\]

Then
\[
\dot{a}_2 = \left[ x_\ast \left(1 - e^\xi\right) + \theta_1 \left(1 - e^\psi\right) \right] \\
\times \left[ a_2 + 4\theta_3 x_\ast \left( e^\xi - 1 \right) e^{2\xi} \right] + 2\theta_2 a_1 e^\xi e^\psi \\
+ 2\theta_3 x_\ast \theta_1 e^{2\xi} \left( e^\psi - 1 \right) \left(1 - e^\xi\right) \\
- 2\theta_2 \theta_3 \left( e^\psi - 1 \right) \left(1 - e^\xi\right)
\]

and so also
\[
\dot{a}_2 = \left[ x_\ast \left(1 - e^\xi\right) + \theta_1 \left(1 - e^\psi\right) \right] a_2 \\
+ \left[ -4a_2^2 e^{2\xi} + 2\theta_1 \theta_2 e^\xi e^\psi \right] a_1 \\
+ 6\theta_3 x_\ast \theta_1 e^{2\xi} \left( e^\psi - 1 \right) \left(1 - e^\xi\right) \\
- 2\theta_2 \theta_3 \left( e^\psi - 1 \right) \left(1 - e^\xi\right).
\]

Taking \(a_3 = -\dot{a}_2\) as before, it readily follows that
\[
\mathcal{M}(\xi, \psi) := a_1(\xi, \psi) + a_2(\xi, \psi) + a_3(\xi, \psi)
\]
is positive definite, so (A.15) satisfies the assumptions of Theorem 1.

ACKNOWLEDGMENTS

The first author acknowledges enlightening discussions with D. Nešić about the importance of local properties of Lyapunov functions.
